

A Calibration

B Decision curve analysis

A Above each panel: calibration slope / intercept for the cross-validated (CV) and temporal (Temp) predictions. The shaded strip shows where the predicted probabilities actually lie. Discrimination survives temporal validation but calibration does not — the intercepts move with the case mix (observation 47.1 → 55.9%, endoscopy 42.0 → 36.3%, surgery 10.9 → 7.7%), so the intercepts would need re-estimating before use in a later period.

B Net benefit from the cross-validated predictions. Shading marks where the model beats both default strategies (observation 0.21–0.75; endoscopy 0.07–0.74; surgery 0.02–0.80). Below those ranges treating everyone as that class is preferable, as expected once the threshold falls under prevalence.
